

Given the following three-dimensional points and their actual labels:

$$\mathbf{x}_A = \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}, \quad y_A = -1$$

$$\mathbf{x}_B = \begin{pmatrix} 3 \\ 3 \\ 1 \end{pmatrix}, \quad y_B = +1$$

$$\mathbf{x}_C = \begin{pmatrix} 4 \\ 3 \\ -1 \end{pmatrix}, \quad y_C = +1$$

If we initial the vector of weights for each dimension (including w_0) as

$$\tilde{\mathbf{w}} = \begin{pmatrix} -3 \\ 2 \\ 2 \\ 0 \end{pmatrix}. \text{ What's the vector of weights using PLA until convergence?}$$

Answer:

Based on the initial weights, we can predict the label of each point as

$$\begin{aligned} \hat{y}_A &= \text{sign}(\tilde{\mathbf{w}}^T \tilde{\mathbf{x}}_A) \\ &= \text{sign} \left(\begin{pmatrix} -3 \\ 2 \\ 2 \\ 0 \end{pmatrix}^T \begin{pmatrix} 1 \\ 1 \\ 1 \\ 0 \end{pmatrix} \right), \text{ where } \hat{y}_A \text{ means the predicted label of A.} \\ &= \text{sign}(-3 \times 1 + 2 \times 1 + 2 \times 1 + 0 \times 0) \\ &= +1 \end{aligned}$$

Since the actual label of A is $y_A = -1$, so the label of A is predicted incorrectly by the initial weights, and PLA uses the input vector of A and its actual label to adjust the vector of weights, as follows:

$$\begin{aligned}
\tilde{\mathbf{W}}_{new} &= \tilde{\mathbf{W}}_{old} + y_A \tilde{\mathbf{x}}_A \\
&= \begin{pmatrix} -3 \\ 2 \\ 2 \\ 0 \end{pmatrix} + (-1) \times \begin{pmatrix} 1 \\ 1 \\ 1 \\ 0 \end{pmatrix} \\
&= \begin{pmatrix} -4 \\ 1 \\ 1 \\ 0 \end{pmatrix}
\end{aligned}$$

Based on the new weights, we can predict the label of each point as

$$\hat{y}_A = \text{sign}(-4 \times 1 + 1 \times 1 + 1 \times 1 + 0 \times 0) = -1,$$

$$\hat{y}_B = \text{sign}(-4 \times 1 + 1 \times 3 + 1 \times 3 + 0 \times 1) = +1,$$

$$\hat{y}_C = \text{sign}(-4 \times 1 + 1 \times 4 + 1 \times 3 - 0 \times 1) = +1.$$

The vector of weights stops updating since the labels of all points are predicted correctly.
